

Decay of ^{61}Cu in oxide and metallic environment

Aleksandra Cvetinović

Department of Low and Medium Energy Physics (F-2)
Jožef Stefan Institute, Slovenia

Motivations and previous results

- For the most radionuclides that decay by electron capture or internal conversion, the probability for these processes is usually insensitive to the nuclear environment
- The decay rate depends only very weakly on the electron wave functions
- Be-7 decays only by electron capture

A. D'Onofrio^d, D. Rogalla^d and F. Terrasi^d

- Kettner et al. predicted a possibility to observe:
 - shorter half-life for α and β^+ -decay
 - longer half-life for β^- -decay and electron capture

If the half-life of radioactive nuclei depends on the electron density at the nucleus due to the physical or the chemical state of the atoms

Different half-life in stellar plasma than in the laboratory

Different probability for nucleosynthesis in stars

Experiment

${}^{60}_{28}\text{Ni} + {}^1_1\text{p} \rightarrow {}^{60}_{29}\text{Cu} + \gamma$ produced in the reaction: ${}^{60}\text{Ni}(p,\gamma){}^{61}\text{Cu}$

- Oxide and metallic nickel targets were activated for 12 hours by proton beam
- Beam energy: 2.48 MeV
- p accelerated by the 2 MV Tandatron accelerator at Jožef Stefan Institute
- Decays were recorded in low-background laboratory every half hour for three days

$3/2^-$ ————— 0.0 $3.333 \text{ H } 5$
 $^{61}_{29}\text{Cu}_{32}$
 $Q(\text{gs}) = 2237.2 \text{ keV } 12$
 $\epsilon: 100\%$

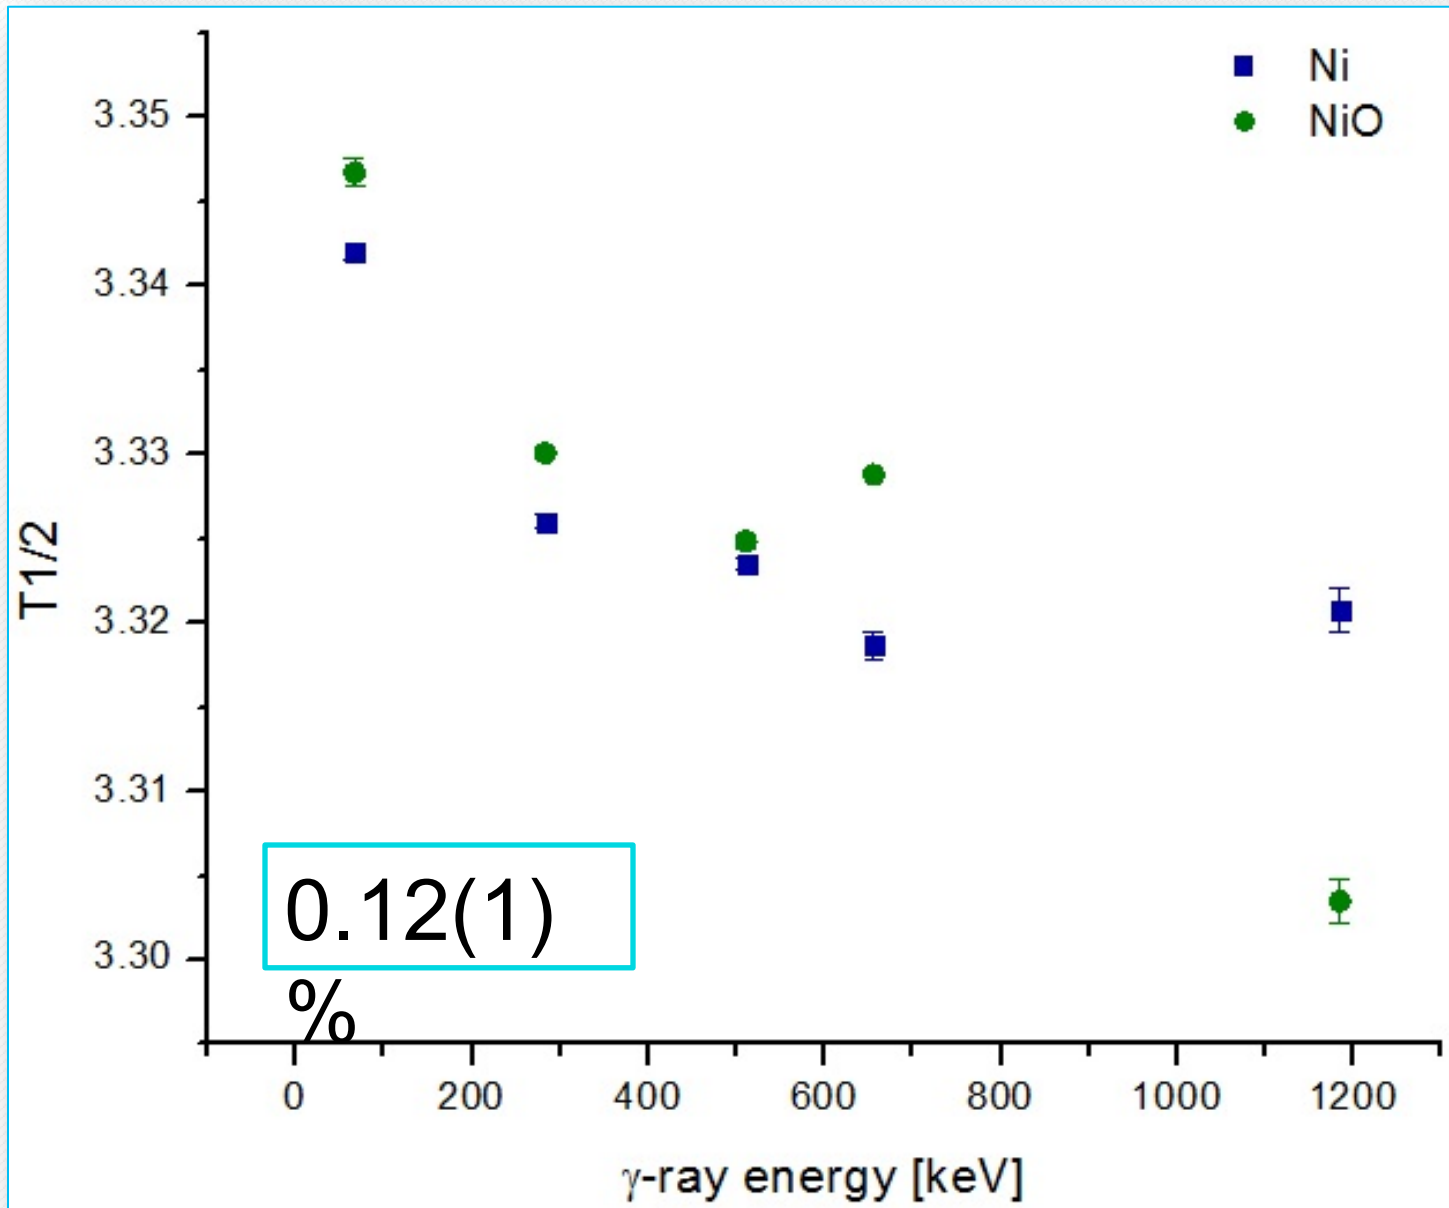

- Half-life is determined from decay law:

$$N(t) = N_0 (1 - e^{-\lambda t}), \quad A = A_0 e^{-\lambda t} \rightarrow 1/2$$

- $N(t)$ is the number of decays occurred at time t

- Table value $T_{1/2}$ of ^{61}Cu : 3.333 (5) h
- Half-life in nickel-oxide: 3.3280 (2) h
- Half-life in nickel: 3.3238 (2) h

- Electronic configuration of nickel in the ground state is: $[\text{Ar}] 3d^8 4s^2$
 - The weakest bound electrons are from shell 4s and over them nickel can build chemical bond with an oxygen atom
 - In NiO this electrons cannot contribute to the electron capture, but in Ni they can
- If we take into account the electron capture from N shell, for the fractional capture probabilities holds:

$$\boxed{A} \downarrow \boxed{A} + \boxed{A} \downarrow \boxed{A} + \boxed{A} \downarrow \boxed{A} + \boxed{A} \downarrow \boxed{A} = 1$$

$$\boxed{A} \downarrow \boxed{A} = \left\{ 1 + \frac{\boxed{A} \downarrow \boxed{A}}{\boxed{A} \downarrow \boxed{A}} \left[1 + \frac{\boxed{A} \downarrow \boxed{A}}{\boxed{A} \downarrow \boxed{A}} \left(1 + \frac{\boxed{A} \downarrow \boxed{A}}{\boxed{A} \downarrow \boxed{A}} \right) \right] \right\}^{\uparrow - 1},$$

$$\boxed{A} \downarrow \boxed{A} = \boxed{A} \downarrow \boxed{A} \left(\frac{\boxed{A} \downarrow \boxed{A}}{\boxed{A} \downarrow \boxed{A}} \right), \quad \boxed{A} \downarrow \boxed{A} = \boxed{A} \downarrow \boxed{A} \left(\frac{\boxed{A} \downarrow \boxed{A}}{\boxed{A} \downarrow \boxed{A}} \right)$$

decay energy (A -value)
- level energy of the final state
- binding energies of the daughter atom

$$\boxed{A} \downarrow \boxed{A} = \boxed{A} \downarrow \boxed{A} \left(\frac{\boxed{A} \downarrow \boxed{A}}{\boxed{A} \downarrow \boxed{A}} \right)^{\uparrow - 1} - \boxed{A} \downarrow \boxed{A} \left(\frac{\boxed{A} \downarrow \boxed{A}}{\boxed{A} \downarrow \boxed{A}} \right)^{\uparrow - 2}$$

$$\frac{A \downarrow A A}{(A)} = \frac{A \downarrow A \downarrow 1 \uparrow 2}{A} \sqrt{\frac{A \downarrow A \uparrow 2}{A \downarrow A \downarrow 1}} \cdot \frac{A (A \downarrow 1)}{A} \cdot [1 + \frac{A \downarrow A \downarrow 2}{A \downarrow A \downarrow 1}],$$

$$\frac{A \downarrow A A}{A (A \downarrow 1)} = \frac{A \downarrow A \downarrow 1 \uparrow 2}{A} \sqrt{\frac{A \downarrow A \downarrow 1 \uparrow 2}{A \downarrow A \downarrow 1}} \cdot \frac{A (A \downarrow 1)}{A} / [1 + \frac{A \downarrow A \downarrow 2}{A \downarrow A \downarrow 1}] / [1 + \frac{A \downarrow A \downarrow 2}{A \downarrow A \downarrow 1}]$$

and

$$\frac{A \downarrow A A}{A \downarrow 1 \uparrow 2} = \frac{A \downarrow A \downarrow 1 \uparrow 2}{A} \sqrt{\frac{A \downarrow A \downarrow 1 \uparrow 2}{A \downarrow A \downarrow 1}} \cdot \frac{A (A \downarrow 1)}{A (A \downarrow 1)} \cdot [1 + \frac{A \downarrow A \downarrow 2}{A \downarrow A \downarrow 1}] / [1 + \frac{A \downarrow A \downarrow 2}{A \downarrow A \downarrow 1}]$$

- $\frac{A \downarrow A \downarrow 1 \uparrow 2}{A} \sqrt{\frac{A \downarrow A \uparrow 2}{A \downarrow A \downarrow 1}}$, etc. – the ratios of the radial wave functions
- $\frac{A (A \downarrow 1)}{A (A)}$, etc. - the ratios of the correction factors for overlap and exchange
- $\frac{A \downarrow A \downarrow 2}{A \downarrow A \downarrow 1}$, etc. are the subshell ratios

Conclusions

- For difference in half-live time in metallic compared to oxide targets from the experiment we got 0.12(1) %
- For the variations in electron densities from the theoretical model we got 0.035(3) %
- We are not sure what is the electronic configuration of copper in the nickel lattice
- In atomic beryllium decay rate is much more sensitive to chemical state of the atoms than in copper

Thank you for your attention!
